# Live-Variable Analysis

- What is Live-Variable Analysis?
  - For each Variable x where is the last program point p where the a specific value of x is used.
  - In other words, for x and program point p determine if the value of x at p
     can still be used along some path starting at p.
    - If so, x is live at p
    - If not x is dead at p
  - Must take Control-Flow into account : a Data-Flow Problem !!!

#### • Applications:

- Register Allocation: If a variable is dead at a given point p
  - Can reuse its storage, i.e, the register it occupies if any;
  - If its value as been modified must save the value to storage unless it is not live on exit of the procedure or loop

# Live-Variable Analysis: Illustration

- At point  $p_0$  the x variable is live:
  - There is a path to  $p_1$  where value at  $p_0$  is used
  - Beyond p<sub>x</sub> towards p<sub>2</sub> the value of x is no longer needed and is dead

- Need to observe for each variable and for each program point:
  - Where is the last program point beyond which the value is not used
  - Trace back from uses to definitions and observe the first definition (backwards) that reaches that use.
  - That definition kills all uses backwards of it.

### Data-Flow Analysis Formulation

- Variable is *live* at a point *p* if its value is used along *at least one*Path
  - A use of x prior to any definition in basic block means x must be alive
  - A definition of x in B prior to any subsequent use means previous uses must be dead
- Gen Set: Set of Variables Used in B
  - Upward Exposed Reads of B
- Kill Set: Set of Variables Defined in B

OUT set

$$OUT(B) = \bigcup_{S \text{ a successor of } B} IN(s)$$

$$IN(B) = Use(B) \cup (OUT(B) - Def(B))$$

### Data-Flow Analysis Formulation

- Initialize IN(B) to Empty Set
- Compute Gen/Use and Kill/Def for each Basic Block
  - Tracing backwards from end of block to beginning of block
  - Initialize Last Instruction's Out(i) to Empty
  - Use  $IN(i) = use(i) \cup (OUT(i) def(i))$
- Iteratively Apply Relations to Basic Block Until Convergence
  - OUT(B) =  $\bigcup_{S \text{ a successor of } B}$
  - $IN(B) = Use(B) \cup (OUT(B) Def(B))$
- Given OUT(B) use relations at instruction level to determine the live variables after each instruction

$$In = Use \cup (Out - Def)$$

$$\{b\}$$

$$OutDef = \{ \}$$

$$OutDef = \{ \}$$

InDef = 
$$\{t, b\}$$

OutDef = 
$$\{b\}$$

$$OutDef = \{ \}$$

- Can be Accomplished by a Forward Scanning of the Block
  - Keep Track of Which Variables are Read before they are written thus computing the Upwards Exposed Reads (UpExp) or Use Function
  - Track Variables that are Written or Killed (VarKill) or Def Function

```
// Assume instruction in format "x \leftarrow y op z"
for i \leftarrow 1 to Num Instructions in B do
  if (instr(i) is leader of B) then
   b \leftarrow Number(B);
   UpExp(b) \leftarrow \emptyset;
   VarKill(b) \leftarrow \emptyset;
  if y \notin VarKill(b) then
   UpExp(b) \leftarrow UpExp(b) \cup \{y\}
  if z \notin VarKill(b) then
   UpExp(b) \leftarrow UpExp(b) \cup \{z\}
  VarKill(b) \leftarrow VarKill(b) \cup \{x\}
```

```
